RSVPs or how I learned how many people will attend your wedding

- \heartsuit Let θ be the true proportion of people that will attend your wedding out of N total invitations that you send.
- \heartsuit Let y be the yes's out of n RSVPs you have received to date.
- \heartsuit We want to know the posterior density of θ given the data y.
- \heartsuit Given θ , the likelihood of getting y yes's and n-y no's is

$$p(y|\theta) \propto \theta^y (1-\theta)^{n-y}$$
.

 \heartsuit A conjugate prior for θ is

$$p(\theta) \propto \theta^{\alpha-1} (1-\theta)^{\beta-1}$$
, where $\theta \sim \text{Beta}(\alpha, \beta)$.

 \heartsuit Using Bayes' rule, the posterior density for θ is

$$p(\theta|y) \propto p(y|\theta)p(\theta)$$

$$= \theta^{y+\alpha-1}(1-\theta)^{n-y+\beta-1}$$

$$= \text{Beta}(\alpha+y,\beta+n-y).$$

 \heartsuit The posterior mean of θ is an average of the prior mean $(\frac{\alpha}{\alpha+\beta})$ and the sample mean $(\frac{y}{n})$:

$$\mathrm{E}(\theta|y) = \frac{\alpha + y}{\alpha + \beta + n}.$$

 \heartsuit The posterior variance of θ is

$$\mathrm{var}(\theta|y) = \frac{(\alpha+y)(\beta+n-y)}{(\alpha+\beta+b)^2(\alpha+\beta+n+1)} = \frac{\mathrm{E}(\theta|y)[1-\mathrm{E}(\theta|y)]}{\alpha+\beta+n+1}.$$

- \heartsuit The prior density is equivalent to having received $\alpha-1$ previous yes's and $\beta-1$ previous no's. As y and n-y grow large compared to α and β , the posterior mean approaches the sample mean and the posterior variance goes to 0 at rate $\frac{1}{n}$.
- ♥ After each response we can update the prior with the previous posterior.

 \heartsuit Suppose there be 5 subgroups such that the prior distribution is a joint distribution of 5 distinct priors:

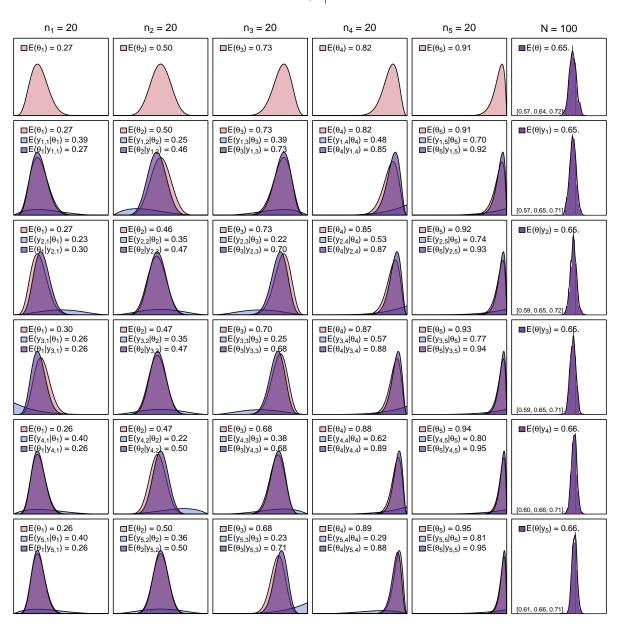

$$p(\theta) = p(\theta_1, \theta_2, \theta_3, \theta_4, \theta_5).$$

 \heartsuit Where the θ s come from the Beta distributions:

$$\begin{array}{c|cccc} p(\theta) = p(\theta_1, \theta_2, \theta_3, \theta_4, \theta_5) & \theta_1 & \theta_2 & \theta_3 & \theta_4 & \theta_5 \\ \hline \alpha & 6 & 11 & 16 & 18 & 20 \\ \beta & 16 & 11 & 6 & 4 & 2 \\ \hline \end{array}$$

- \heartsuit Each subgroup represents expected responses from $n=\alpha+\beta-2=20$ people.
- \heartsuit The joint distributions can be computed by taking 1000 samples from each of the subgroup prior distributions.
- \circ How will the posterior distributions update if you receive the following data? Each column represents responses associated with a given subgroup. Each row is the number of yes's out of 4 invitations received over time.

$$\begin{array}{c|ccccc} p(\theta) = p(\theta_1, \theta_2, \theta_3, \theta_4, \theta_5) & \theta_1 & \theta_2 & \theta_3 & \theta_4 & \theta_5 \\ \hline \alpha & 6 & 11 & 16 & 18 & 20 \\ \beta & 16 & 11 & 6 & 4 & 2 \\ \hline \end{array}$$

$$y = \begin{bmatrix} 1 & 1 & 3 & 4 & 4 \\ 2 & 2 & 2 & 4 & 4 \\ 0 & 2 & 2 & 4 & 4 \\ 1 & 3 & 3 & 4 & 4 \\ 1 & 2 & 4 & 3 & 4 \end{bmatrix}$$
